

Net Zero Needs Nuclear

Nuclear for Climate is an initiative gathering nuclear professionals and scientists from over 150 societies and associations, with the goal of opening a dialogue with policymakers and the public about the necessity of including nuclear energy among the carbon-free solutions to climate change.

We have a **vision** of a clean, sustainable and abundant low-carbon future for all. Our **mission** is to accelerate the ability of the world to achieve Net Zero by 2050, by driving collaboration between nuclear and renewable technology. We believe that **Net Zero Needs Nuclear** and these are the reasons why:

- **Nuclear is a proven and effective low carbon energy source:** Nuclear reduces greenhouse gas emissions and can replace our current reliance on polluting fossil fuel sources.
- **Nuclear is available, scalable and deployable:** New nuclear needs to be deployed at scale and urgently, along with renewables, in order for Net Zero targets to be achievable.
- **Nuclear is a flexible, affordable and secure source of clean energy:** Nuclear can integrate with an increasing supply of variable renewables to deliver efficient, affordable and secure clean energy systems.
- **Nuclear can deliver more than just low carbon electricity:** Nuclear is also capable of supporting the decarbonisation of other sectors, such as heating and transport.
- **Nuclear supports inclusive and sustainable global development:** Nuclear promotes global socio-economic benefits and is strongly aligned to the UN Sustainable Development Goals.

Six years on from the signing of the Paris Agreement, we are waking up to the enormity of the challenge that the world faces in limiting global temperature rise to 1.5°C above pre-industrial levels. The global climate is at a critical juncture and together, we need to reach Net Zero carbon emissions by no later than 2050 if we are to have a chance of achieving this and protecting our planet's future. But we are off track, and time is running out. So we need to act now.

The 26th annual Conference of the Parties (COP26) in Glasgow represents a critical opportunity for our nations to come together and take action, collectively changing the way we think about climate and setting us on the path towards achieving Net Zero.

We are calling on all negotiators and policy makers who are involved at COP26 to take a scientific and technology neutral approach to energy policy and financing that can promote sustainable collaboration between nuclear and renewables.

Nuclear is a proven and effective low carbon energy source: Nuclear reduces greenhouse gas emissions and can replace our current reliance on polluting fossil fuel sources.

- Nuclear has been a key low carbon energy source for over 60 years. With around 440 reactors currently operable across over 30 different countries, and 52 further under construction, nuclear accounted for 10% of global electricity production at the end of 2020¹. It is the second largest global source of low carbon energy, after hydropower.
- The relative lifecycle CO₂ emissions of nuclear are very low, similar to that of wind and hydropower². A life cycle assessment of nuclear power produced in Sweden has shown a carbon intensity of 2.5g CO₂/kWh³, making it one of the world's cleanest energy sources. The countries which have the lowest carbon intensity are those with a large component of nuclear and hydropower. France produces approximately three quarters of its electricity from nuclear, more than any other country in the world. As a result, it, has the lowest per capita emissions of the seven largest industrialised countries (G7).
- As a direct result of nuclear replacing fossil fuel sources, more than 60Gt⁴ of CO₂ equivalent greenhouse gas emissions have been avoided globally since 1970. Using nuclear instead of fossil fuels has also prevented an estimated 1.84 million air pollution related deaths and it is estimated that a further 7 million deaths could be avoided by 2050 if nuclear replaced fossil fuel sources on a large scale⁵.
- Despite the impressive global (5x) growth of solar and wind between 2010 and 2019, the use of fossil fuels has remained constant, representing roughly 80% of the total global energy supply. This correlates with a decline in the share of nuclear generation over this time period⁶, even though nuclear generation in absolute terms has increased.
- Countries which have shut down their nuclear plants over recent years have struggled to reduce their reliance on polluting fossil fuels. Following a planned nuclear phaseout in Germany, their percentage share of fossil fuels as a primary energy source has dropped by less than 1% since 2010⁷ despite a massive investment in the growth of renewable sources (€178 Bn)⁸.
- Nuclear is currently excluded from various national and international sustainable finance mechanisms. However, an assessment by the Joint Research Centre (JRC), whose mission is to support EU policies with independent evidence throughout the whole policy cycle, has found that “there is no science-based evidence that nuclear energy does more harm to human health or to the environment than other electricity production technologies already included in the EU Taxonomy as activities supporting climate change mitigation.”⁹ Two accompanying expert opinions have confirmed the conclusions of the JRC^{10,11}.

Nuclear is available, scalable and deployable: New nuclear needs to be deployed at scale and urgently, along with renewables, in order for Net Zero targets to be achievable.

- The consensus across major international institutions (UN, OECD-IEA¹², EU¹³) is that all low carbon technologies, including nuclear, will need to be deployed urgently and at scale in order to achieve Net Zero targets. A recent United Nations Economic Commission for Europe (UNECE) report¹⁴ indicated that “the world’s climate objectives will not be met if nuclear technologies are excluded.” This is also reflected in the IPCC’s special report ¹⁵ which indicates through their ‘middle-of-the-road’ scenario that a six-fold increase of the current nuclear supply is required by 2050 in order to limit global temperature rise to 1.5°C.
- Nuclear is an available and scalable technology which has been deployed rapidly to positive effect in the past. Over the past 50 years, new nuclear projects have represented the fastest method of achieving decarbonisation in terms of clean energy added per capita annually. This is reflected by the Swedish nuclear program where, from 1970, 10.9 GWe of new nuclear capacity was added in less than 15 years¹⁶. Swedish CO₂ emissions per capita have decreased by 75% since 1970¹⁷.
- Small Modular Reactors (SMRs) have the potential to bolster new large nuclear projects and to support other clean technology technologies such as renewables and hydrogen production. With the promise of reducing on-site construction time through modular manufacture of components, SMRs offer the possibility of increased scalability of deployment as well as reduced capital costs and associated financial risk, once established. Certain leading nuclear nations project that both small and large nuclear projects can contribute towards achieving Net Zero^{18,19}.
- Due to the massive energy density of uranium and other fissile fuels, nuclear plants require a very small amount of land relative to the clean energy that they produce. In fact, nuclear has the lowest land use intensity of all the primary energy sources at 0.1m²/MWh, an order of magnitude less than that of other clean energy sources²⁰.

Nuclear is a flexible, affordable and secure source of clean energy: Nuclear can integrate with an increasing supply of variable renewables to deliver efficient, affordable and secure clean energy systems.

- Deployment of renewables has risen rapidly and must continue to do so. However, this increases the volatility of energy systems and introduces a greater requirement for grid flexibility²¹. Nuclear is a secure source of clean energy which is both dispatchable and flexible and can integrate with variable renewables whilst reducing dependency on imported fossil fuels²².
- There are ongoing developments to further improve the operational flexibility and efficiency of nuclear reactors through design, as well as through more diverse application. This

includes applying nuclear as a method of clean energy storage within hybrid systems by utilising nuclear-generated process heat or hydrogen²³.

- New technologies, including SMRs, offer the potential for more widespread and dispersed integration with renewables and other clean energy sources, supporting a more decentralised system where required, and bringing supply closer to points of demand.
- Recent research has shown that nuclear remains the cheapest dispatchable low-carbon technology²⁴ and the cost of decarbonising electricity is lowest when the mix includes optimal amounts of this type of clean and consistent generation capacity²⁵. Another recent study finds that nuclear is the clean energy source with the highest system value for reducing carbon intensity²⁶. System value is an important holistic measure which quantifies the total impact of each source upon the wider energy system.

Nuclear can deliver more than just low carbon electricity: Nuclear is also capable of supporting the decarbonisation of other sectors, such as heating and transport.

- Global electricity production, which is projected to increase significantly, currently accounts for 40% of total greenhouse gas emissions and it is still dominated by fossil fuel sources (64% of total electricity production)²⁷. Fossil fuels are also used extensively across other sectors such as transport, heating and industrial processes.
- Nuclear has the ability to produce hydrogen effectively, which can then be used as an alternative to fossil fuels to support wider decarbonisation^{28,29}. Nuclear-produced hydrogen can also be used in clean energy systems to add further grid flexibility. The concept of a clean hydrogen economy is receiving political and business momentum, with the number of associated policies and projects around the world expanding rapidly³⁰.
- Nuclear reactors also have the ability to supply heat to support more diverse non-electric applications that would provide economic, environmental and efficiency-related benefits³¹. These wider 'cogeneration' applications can include, amongst others, district heating, industrial process heat and seawater desalination³².
- New advanced reactors being developed with higher operating temperatures also have the potential to provide further clean alternatives to other non-electric, energy-intensive applications including: polymer and plastic production, blast furnacing, agriculture fertilizer production as well as more efficient hydrogen production from high temperature electrolysis or thermochemical methods³³.

Nuclear supports inclusive and sustainable global development: Nuclear promotes global socio-economic benefits and is strongly aligned to the UN Sustainable Development Goals.

- UNECE recognises Nuclear as an "indispensable tool" when it comes to achieving the UN Sustainable Development Goals (SDGs)³⁴. It can drive the decarbonisation of the energy sector, reduce energy poverty and directly target a range of other SDGs, including: the

elimination of poverty, zero hunger, clean water, affordable energy, economic growth and industry innovation.

- Nuclear can play a key role in emerging markets by delivering affordable clean energy whilst supporting high living standards and a sustainable economy³⁵. As a result, more than 30 new countries are currently planning or establishing nuclear power programmes and over 20 more have expressed serious interest in the technology. Bangladesh, Belarus, the UAE and Turkey are in the process of building, or have recently begun operating their first reactors and a range of further countries in emerging markets are considering nuclear development as a clean energy solution³⁶.
- According to the IEA, new nuclear capacity of 15 GWe is required on average every year between 2020 and 2040 in order to meet their projected, SDG aligned, Sustainable Development Scenario (SDS). This will be critical for securing a cleaner and more inclusive energy future³⁷.
- Nuclear delivers skilled jobs and economic benefits. A recent study on the European economy found that every Euro spent on nuclear generates an additional 5 Euros in EU Gross Domestic Product (GDP), and every direct job created in the nuclear industry creates 3.2 jobs in the EU economy as a whole³⁸.
- For these reasons, new nuclear can directly facilitate the global post COVID-19 recovery process: creating long term jobs and promoting sustainable economic development whilst increasing energy resilience and driving forward the clean energy transition³⁹.
